3

**LIDOCAINE HYDROCHLORIDE**

4

*INJECTION, USP*

5

Rx only

6

**Local Anesthetic for Infiltration and Nerve Block**

7

**Not for Spinal or Epidural Anesthesia**

8

**DESCRIPTION:**

9

Lidocaine Hydrochloride Injection, USP is a local anesthetic which is a sterile,

10

nonpyrogenic solution intended for parenteral injection. See **INDICATIONS**

11

**AND USAGE** for specific uses.

12

Lidocaine hydrochloride is chemically designated as 2-(Diethylamino)-2',

13

6'-acetoxylidide monohydrochloride and has the following structural formula:

14

15

**C<sub>14</sub>H<sub>22</sub>N<sub>2</sub>O • HCl**

**M.W. 288.82**

16

Each mL contains: Lidocaine hydrochloride 10 or 20 mg; methylparaben

17

0.1%; sodium chloride (7 mg and 6 mg of sodium chloride for 1% and 2%

1 respectively) to render it isotonic; Water for Injection q.s. Hydrochloric acid  
2 and/or sodium hydroxide may have been added for pH adjustment (5.0 to 7.0).

### 3 **CLINICAL PHARMACOLOGY:**

#### 4 *Mechanism of Action*

5 Lidocaine HCl stabilizes the neuronal membrane by inhibiting the ionic fluxes  
6 required for the initiation and conduction of impulses, thereby effecting local  
7 anesthetic action.

#### 8 *Hemodynamics*

9 Excessive blood levels may cause changes in cardiac output, total peripheral  
10 resistance, and mean arterial pressure. With central neural blockade these changes  
11 may be attributable to block of autonomic fibers, a direct depressant effect of the  
12 local anesthetic agent on various components of the cardiovascular system. The  
13 net effect is normally a modest hypotension when the recommended dosages are  
14 not exceeded.

#### 15 *Pharmacokinetics and Metabolism*

16 Information derived from diverse formulations, concentrations and usages reveals  
17 that lidocaine HCl is completely absorbed following parenteral administration, its  
18 rate of absorption depending, for example, upon various factors such as the site of  
19 administration and the presence or absence of a vasoconstrictor agent. Except for  
20 intravascular administration, the highest blood levels are obtained following  
21 intercostal nerve block and the lowest after subcutaneous administration.

22         The plasma binding of lidocaine HCl is dependent on drug concentration,  
23 and the fraction bound decreases with increasing concentration. At concentrations

1 of 1 to 4 mcg of free base/mL, 60 to 80% of lidocaine HCl is protein bound.

2 Binding is also dependent on the plasma concentration of the alpha-1-acid

3 glycoprotein.

4 Lidocaine HCl crosses the blood-brain and placental barriers, presumably

5 by passive diffusion.

6 Lidocaine HCl is metabolized rapidly by the liver, and metabolites and

7 unchanged drug are excreted by the kidneys. Biotransformation includes oxidative

8 N-dealkylation, ring hydroxylation, cleavage of the amide linkage, and

9 conjugation. N-dealkylation, a major pathway of biotransformation, yields the

10 metabolites monoethylglycinexylidide and glycinexylidide. The

11 pharmacological/toxicological actions of these metabolites are similar to, but less

12 potent than, those of lidocaine HCl. Approximately 90% of lidocaine HCl

13 administered is excreted in the form of various metabolites, and less than 10% is

14 excreted unchanged. The primary metabolite in urine is a conjugate of 4-hydroxy-

15 2,6-dimethylaniline.

16 The elimination half-life of lidocaine HCl following an intravenous bolus

17 injection is typically 1.5 to 2 hours. Because of the rapid rate at which lidocaine

18 HCl is metabolized, any condition that affects liver function may alter lidocaine

19 kinetics. The half-life may be prolonged two-fold or more in patients with liver

20 dysfunction. Renal dysfunction does not affect lidocaine HCl kinetics but may

21 increase the accumulation of metabolites.

22 Factors such as acidosis and the use of CNS stimulants and depressants

23 affect the CNS levels of lidocaine HCl required to produce overt systemic effects.

1 Objective adverse manifestations become increasingly apparent with increasing  
2 venous plasma levels above 6 mcg free base/mL. In the rhesus monkey arterial  
3 blood levels of 18 to 21 mcg/mL have been shown to be threshold for convulsive  
4 activity.

5 **INDICATIONS AND USAGE:**

6 Lidocaine Hydrochloride Injection, USP is indicated for the production of local  
7 anesthesia, by infiltration techniques, such as percutaneous injection, and by  
8 peripheral nerve block techniques, such as brachial plexus and inter-costal, when  
9 the accepted procedures for these techniques as described in standard textbooks are  
10 observed.

11 **CONTRAINDICATIONS:**

12 Lidocaine HCl is contraindicated in patients with a known history of  
13 hypersensitivity to local anesthetics of the amide type.

14 **WARNINGS:**

15 LIDOCAINE HYDROCHLORIDE INJECTION FOR INFILTRATION AND  
16 NERVE BLOCK SHOULD BE EMPLOYED ONLY BY CLINICIANS WHO  
17 ARE WELL VERSED IN DIAGNOSIS AND MANAGEMENT OF DOSE-  
18 RELATED TOXICITY AND OTHER ACUTE EMERGENCIES THAT MIGHT  
19 ARISE FROM THE BLOCK TO BE EMPLOYED AND THEN ONLY AFTER  
20 ENSURING THE *IMMEDIATE* AVAILABILITY OF OXYGEN, OTHER  
21 RESUSCITATIVE DRUGS, CARDIOPULMONARY EQUIPMENT AND THE  
22 PERSONNEL NEEDED FOR PROPER MANAGEMENT OF TOXIC

1 REACTIONS AND RELATED EMERGENCIES (see also **ADVERSE**  
2 **REACTIONS** and **PRECAUTIONS**). DELAY IN PROPER MANAGEMENT  
3 OF DOSE-RELATED TOXICITY, UNDERVENTILATION FROM ANY  
4 CAUSE AND/OR ALTERED SENSITIVITY MAY LEAD TO THE  
5 DEVELOPMENT OF ACIDOSIS, CARDIAC ARREST AND, POSSIBLY,  
6 DEATH.

7           Intra-articular infusions of local anesthetics following arthroscopic and other  
8 surgical procedures is an unapproved use, and there have been post-marketing  
9 reports of chondrolysis in patients receiving such infusions. The majority of  
10 reported cases of chondrolysis have involved the shoulder joint; cases of gleno-  
11 humeral chondrolysis have been described in pediatric and adult patients following  
12 intra-articular infusions of local anesthetics with and without epinephrine for periods  
13 of 48 to 72 hours. There is insufficient information to determine whether shorter  
14 infusion periods are not associated with these findings. The time of onset of  
15 symptoms, such as joint pain, stiffness and loss of motion can be variable, but may  
16 begin as early as the 2nd month after surgery. Currently, there is no effective  
17 treatment for chondrolysis; patients who experienced chondrolysis have required  
18 additional diagnostic and therapeutic procedures and some required arthroplasty or  
19 shoulder replacement.

20           To avoid intravascular injection, aspiration should be performed before the  
21 local anesthetic solution is injected. The needle must be repositioned until no  
22 return of blood can be elicited by aspiration. Note, however, that the absence of

1 blood in the syringe does not guarantee that intravascular injection has been  
2 avoided.

3           Local anesthetic solutions containing antimicrobial preservatives (e.g.,  
4 methylparaben) should not be used for epidural or spinal anesthesia because the  
5 safety of these agents has not been established with regard to intrathecal injection,  
6 either intentional or accidental.

## 7 **PRECAUTIONS:**

### 8 ***General***

9 The safety and effectiveness of lidocaine HCl depend on proper dosage, correct  
10 technique, adequate precautions, and readiness for emergencies. Standard  
11 textbooks should be consulted for specific techniques and precautions for various  
12 regional anesthetic procedures.

13           Resuscitative equipment, oxygen, and other resuscitative drugs should be  
14 available for immediate use (see **WARNINGS** and **ADVERSE REACTIONS**).

15 The lowest dosage that results in effective anesthesia should be used to avoid high  
16 plasma levels and serious adverse effects. Syringe aspirations should also be  
17 performed before and during each supplemental injection when using indwelling  
18 catheter techniques. An intravascular injection is still possible even if aspirations  
19 for blood are negative. Repeated doses of lidocaine HCl may cause significant  
20 increases in blood levels with each repeated dose, because of slow accumulation of  
21 the drug or its metabolites. Tolerance to elevated blood levels varies with the  
22 status of the patient. Debilitated, elderly patients, acutely ill patients, and children  
23 should be given reduced doses commensurate with their age and physical

1 condition. Lidocaine HCl should also be used with caution in patients with severe  
2 shock or heart block.

3 Careful and constant monitoring of cardiovascular and respiratory  
4 (adequacy of ventilation) vital signs and the patient's state of consciousness should  
5 be accomplished after each local anesthetic injection. It should be kept in mind at  
6 such times that restlessness, anxiety, tinnitus, dizziness, blurred vision, tremors,  
7 depression or drowsiness may be early warning signs of central nervous system  
8 toxicity.

9 Since amide-type local anesthetics are metabolized by the liver, lidocaine  
10 HCl should be used with caution in patients with hepatic disease. Patients with  
11 severe hepatic disease, because of their inability to metabolize local anesthetic  
12 normally, are at greater risk of developing toxic plasma concentrations. Lidocaine  
13 HCl should also be used with caution in patients with impaired cardiovascular  
14 function since they may be less able to compensate for functional changes  
15 associated with the prolongation of A-V conduction produced by these drugs.

16 Many drugs used during the conduct of anesthesia are considered potential  
17 triggering agents for familial malignant hyperthermia. Since it is not known  
18 whether amide-type local anesthetics may trigger this reaction and since the need  
19 for supplemental general anesthesia cannot be predicted in advance, it is suggested  
20 that a standard protocol for the management of malignant hyperthermia should be  
21 available. Early unexplained signs of tachycardia, tachypnea, labile blood pressure  
22 and metabolic acidosis may precede temperature elevation. Successful outcome is  
23 dependent on early diagnosis, prompt discontinuance of the suspect triggering

1 agent(s) and institution of treatment, including oxygen therapy, indicated  
2 supportive measures and dantrolene (consult dantrolene sodium intravenous  
3 package insert before using).

4 Lidocaine HCl should be used with caution in persons with known drug  
5 sensitivities. Patients allergic to para-aminobenzoic acid derivatives (procaine,  
6 tetracaine, benzocaine, etc.) have not shown cross-sensitivity to lidocaine HCl.

### 7 *Use in the Head and Neck Area*

8 Small doses of local anesthetics injected into the head and neck area, including  
9 retrobulbar, dental and stellate ganglion blocks, may produce adverse reactions  
10 similar to systemic toxicity seen with unintentional intravascular injections of  
11 larger doses. Confusion, convulsions, respiratory depression and/or respiratory  
12 arrest, and cardiovascular stimulation or depression have been reported. These  
13 reactions may be due to intra-arterial injection of the local anesthetic with  
14 retrograde flow to the cerebral circulation. Patients receiving these blocks should  
15 have their circulation and respiration monitored and be constantly observed.  
16 Resuscitative equipment and personnel for treating adverse reactions should be  
17 immediately available. Dosage recommendations should not be exceeded (see  
18 **DOSAGE AND ADMINISTRATION**).

### 19 *Clinically Significant Drug Interactions*

20 Concurrent administration of vasopressor drugs (for the treatment of hypotension  
21 related to obstetric blocks) and ergot-type oxytocic drugs may cause severe,  
22 persistent hypertension or cerebrovascular accidents.

23

1 ***Drug /Laboratory Test Interactions***

2 The intramuscular injection of lidocaine HCl may result in an increase in creatine  
3 phosphokinase levels. Thus, the use of this enzyme determination, without  
4 isoenzyme separation, as a diagnostic test for the presence of acute myocardial  
5 infarction may be compromised by the intramuscular injection of lidocaine HCl.

6 ***Carcinogenesis, Mutagenesis, Impairment of Fertility***

7 Studies of lidocaine HCl in animals to evaluate the carcinogenic and mutagenic  
8 potential or the effect on fertility have not been conducted.

9 ***Pregnancy***

10 **Teratogenic Effects: Pregnancy Category B**

11 Reproduction studies have been performed in rats at doses up to 6.6 times the  
12 human dose and have revealed no evidence of harm to the fetus caused by  
13 lidocaine HCl. There are, however, no adequate and well-controlled studies in  
14 pregnant women. Animal reproduction studies are not always predictive of human  
15 response. General consideration should be given to this fact before administering  
16 lidocaine HCl to women of childbearing potential, especially during early  
17 pregnancy when maximum organogenesis takes place.

18 ***Labor and Delivery***

19 Local anesthetics rapidly cross the placenta and when used for epidural,  
20 paracervical, pudendal, or caudal block anesthesia, can cause varying degrees of  
21 maternal, fetal and neonatal toxicity (see **CLINICAL PHARMACOLOGY-**  
22 ***Pharmacokinetics and Metabolism***). The potential for toxicity depends upon the  
23 procedure performed, the type and amount of drug used, and the technique of drug

1 administration. Adverse reactions in the parturient, fetus and neonate involve  
2 alterations of the central nervous system, peripheral vascular tone and cardiac  
3 function.

4           Local anesthetics produce vasodilation by blocking sympathetic nerves.  
5 Elevating the patient's legs and positioning her on her left side will help prevent  
6 decreases in blood pressure. The fetal heart rate also should be monitored  
7 continuously, and electronic fetal monitoring is highly advisable.

8           Paracervical or pudendal anesthesia may alter the forces of parturition  
9 through changes in uterine contractility or maternal expulsive efforts. In one study  
10 paracervical block anesthesia was associated with a decrease in the mean duration  
11 of first stage labor and facilitation of cervical dilation. The use of obstetrical  
12 anesthesia may increase the need for forceps assistance.

13           The use of some local anesthetic drug products during labor and delivery  
14 may be followed by diminished muscle strength and tone for the first day or two of  
15 life. The long-term significance of these observations is unknown. Fetal  
16 bradycardia may occur in 20 to 30% of patients receiving paracervical nerve block  
17 anesthesia with the amide-type local anesthetics and may be associated with fetal  
18 acidosis. Fetal heart rate should always be monitored during paracervical  
19 anesthesia. The physician should weigh the possible advantages against risks when  
20 considering a paracervical block in prematurity, toxemia of pregnancy, and fetal  
21 distress. Careful adherence to recommended dosage is of the utmost importance in  
22 obstetrical paracervical block. Failure to achieve adequate analgesia with  
23 recommended doses should arouse suspicion of intravascular or fetal intracranial

1 injection. Cases compatible with unintended fetal intracranial injection of local  
2 anesthetic solution have been reported following intended paracervical or pudendal  
3 block or both. Babies so affected present with unexplained neonatal depression at  
4 birth, which correlates with high local anesthetic serum levels, and often manifest  
5 seizures within six hours. Prompt use of supportive measures combined with  
6 forced urinary excretion of the local anesthetic has been used successfully to  
7 manage this complication.

8 Case reports of maternal convulsions and cardiovascular collapse following  
9 use of some local anesthetics for paracervical block in early pregnancy (as  
10 anesthesia for elective abortion) suggest that systemic absorption under these  
11 circumstances may be rapid. The recommended maximum dose of each drug  
12 should not be exceeded. Injection should be made slowly and with frequent  
13 aspiration. Allow a 5-minute interval between sides.

#### 14 *Nursing Mothers*

15 It is not known whether this drug is excreted in human milk. Because many drugs  
16 are excreted in human milk, caution should be exercised when lidocaine HCl is  
17 administered to a nursing woman.

#### 18 *Pediatric Use*

19 Dosages in children should be reduced, commensurate with age, body weight and  
20 physical condition (see **DOSAGE AND ADMINISTRATION**).

21

22

23

1 **ADVERSE REACTIONS:**

2 *Systemic*

3 Adverse experiences following the administration of lidocaine HCl are similar in  
4 nature to those observed with other amide local anesthetic agents. These adverse  
5 experiences are, in general, dose-related and may result from high plasma levels  
6 caused by excessive dosage, rapid absorption or inadvertent intravascular injection,  
7 or may result from a hypersensitivity, idiosyncrasy or diminished tolerance on the  
8 part of the patient. Serious adverse experiences are generally systemic in nature.

9 The following types are those most commonly reported:

10 *Central Nervous System*

11 CNS manifestations are excitatory and/or depressant and may be characterized by  
12 lightheadedness, nervousness, apprehension, euphoria, confusion, dizziness,  
13 drowsiness, tinnitus, blurred or double vision, vomiting, sensations of heat, cold or  
14 numbness, twitching, tremors, convulsions, unconsciousness, respiratory  
15 depression and arrest. The excitatory manifestations may be very brief or may not  
16 occur at all, in which case the first manifestation of toxicity may be drowsiness  
17 merging into unconsciousness and respiratory arrest.

18 Drowsiness following the administration of lidocaine HCl is usually an  
19 early sign of a high blood level of the drug and may occur as a consequence of  
20 rapid absorption.

21

22

23

1    ***Cardiovascular System***

2    Cardiovascular manifestations are usually depressant and are characterized by  
3    bradycardia, hypotension, and cardiovascular collapse, which may lead to cardiac  
4    arrest.

5    ***Allergic***

6    Allergic reactions are characterized by cutaneous lesions, urticaria, edema or  
7    anaphylactoid reactions. Allergic reactions may occur as a result of sensitivity  
8    either to local anesthetic agents or to the methylparaben used as a preservative in  
9    the multiple dose vials. Allergic reactions as a result of sensitivity to lidocaine HCl  
10   are extremely rare and, if they occur, should be managed by conventional means.  
11   The detection of sensitivity by skin testing is of doubtful value.

12   ***Neurologic***

13   The incidences of adverse reactions associated with the use of local anesthetics  
14   may be related to the total dose of local anesthetic administered and are also  
15   dependent upon the particular drug used, the route of administration and the  
16   physical status of the patient. In a prospective review of 10,440 patients who  
17   received lidocaine HCl for spinal anesthesia, the incidences of adverse reactions  
18   were reported to be about 3% each for positional headaches, hypotension and  
19   backache; 2% for shivering; and less than 1% each for peripheral nerve symptoms,  
20   nausea, respiratory inadequacy and double vision. Many of these observations may  
21   be related to local anesthetic techniques, with or without a contribution from the  
22   local anesthetic.

1           There have been reported cases of permanent injury to extraocular muscles  
2 requiring surgical repair following retrobulbar administration.

3   **OVERDOSAGE:**

4   Acute emergencies from local anesthetics are generally related to high plasma  
5 levels encountered during therapeutic use of local anesthetics or to unintended  
6 subarachnoid injection of local anesthetic solution (see **ADVERSE REACTIONS,**  
7 **WARNINGS** and **PRECAUTIONS**).

8   ***Management of Local Anesthetic Emergencies***

9   The first consideration is prevention, best accomplished by careful and constant  
10 monitoring of cardiovascular and respiratory vital signs and the patient's state of  
11 consciousness after each local anesthetic injection. At the first sign of change,  
12 oxygen should be administered.

13           The first step in the management of convulsions, as well as underventilation  
14 or apnea due to unintended subarachnoid injection of drug solution, consists of  
15 immediate attention to the maintenance of a patent airway and assisted or  
16 controlled ventilation with oxygen and a delivery system capable of permitting  
17 immediate positive airway pressure by mask. Immediately after the institution of  
18 these ventilatory measures, the adequacy of the circulation should be evaluated,  
19 keeping in mind that drugs used to treat convulsions sometimes depress the  
20 circulation when administered intravenously. Should convulsions persist despite  
21 adequate respiratory support, and if the status of the circulation permits, small  
22 increments of an ultra-short acting barbiturate (such as thiopental or thiamylal) or a  
23 benzodiazepine (such as diazepam) may be administered intravenously. The

1 clinician should be familiar, prior to the use of local anesthetics, with these  
2 anticonvulsant drugs. Supportive treatment of circulatory depression may require  
3 administration of intravenous fluids and, when appropriate, a vasopressor as  
4 directed by the clinical situation (e.g., ephedrine).

5         If not treated immediately, both convulsions and cardiovascular depression  
6 can result in hypoxia, acidosis, bradycardia, arrhythmias and cardiac arrest.

7 Underventilation or apnea due to unintentional subarachnoid injection of local  
8 anesthetic solution may produce these same signs and also lead to cardiac arrest if  
9 ventilatory support is not instituted. If cardiac arrest should occur, standard  
10 cardiopulmonary resuscitative measures should be instituted.

11         Endotracheal intubation, employing drugs and techniques familiar to the  
12 clinician, may be indicated, after initial administration of oxygen by mask, if  
13 difficulty is encountered in the maintenance of a patent airway or if prolonged  
14 ventilatory support (assisted or controlled) is indicated. Dialysis is of negligible  
15 value in the treatment of acute overdose with lidocaineHCl.

16         The oral LD<sub>50</sub> of lidocaine HCl in non-fasted female rats is 459 (346 to  
17 773) mg/kg (as the salt) and 214 (159 to 324) mg/kg (as the salt) in fasted female  
18 rats.

## 19 **DOSAGE AND ADMINISTRATION:**

20 **Table 1** (Recommended Dosages) summarizes the recommended volumes and  
21 concentrations of lidocaine hydrochloride injection for various types of anesthetic  
22 procedures. The dosages suggested in this table are for normal healthy adults and  
23 refer to the use of epinephrine-free solutions. When larger volumes are required,

1 only solutions containing epinephrine should be used, except in those cases where  
2 vasopressor drugs may be contraindicated.

3         There have been adverse event reports of chondrolysis in patients receiving  
4 intra-articular infusions of local anesthetics following arthroscopic and other  
5 surgical procedures. Lidocaine is not approved for this use (see **WARNINGS** and  
6 **DOSAGE AND ADMINISTRATION**).

7         These recommended doses serve only as a guide to the amount of anesthetic  
8 required for most routine procedures. The actual volumes and concentrations to be  
9 used depend on a number of factors such as type and extent of surgical procedure,  
10 depth of anesthesia and degree of muscular relaxation required, duration of  
11 anesthesia required and the physical condition of the patient. In all cases the  
12 lowest concentration and smallest dose that will produce the desired result should  
13 be given. Dosages should be reduced for children and for elderly and debilitated  
14 patients and patients with cardiac and/or liver disease.

15         The onset of anesthesia, the duration of anesthesia and the degree of  
16 muscular relaxation are proportional to the volume and concentration (i.e. total  
17 dose) of local anesthetic used. Thus, an increase in volume and concentration of  
18 lidocaine hydrochloride injection will decrease the onset of anesthesia, prolong the  
19 duration of anesthesia, provide a greater degree of muscular relaxation and increase  
20 the segmental spread of anesthesia. However, increasing the volume and  
21 concentration of lidocaine hydrochloride injection may result in a more profound  
22 fall in blood pressure when used in epidural anesthesia. Although the incidence of  
23 side effects with lidocaine is quite low, caution should be exercised when

1 employing large volumes and concentrations, since the incidence of side effects is  
2 directly proportional to the total dose of local anesthetic agent injected.

3 **MAXIMUM RECOMMENDED DOSAGES:**

4 **NOTE: The products accompanying this insert do not contain epinephrine.**

5 *Adults*

6 For normal healthy adults, the individual maximum recommended dose of  
7 lidocaine hydrochloride without epinephrine should not exceed 4.5 mg/kg (2  
8 mg/lb) of body weight and in general it is recommended that the maximum total  
9 dose does not exceed 300 mg.

10       The maximum recommended dose per 90 minute period of lidocaine  
11 hydrochloride for paracervical block in obstetrical and non-obstetrical patients is  
12 200 mg total. One half of the total dose is usually administered to each side. Inject  
13 slowly, five minutes between sides (see also discussion of paracervical block in  
14 **PRECAUTIONS**).

**TABLE 1**  
**RECOMMENDED DOSAGES OF LIDOCAINE HYDROCHLORIDE INJECTION**  
**(WITHOUT EPINEPHRINE)**  
**FOR VARIOUS ANESTHETIC PROCEDURES IN NORMAL HEALTHY ADULTS**

<b>LIDOCAINE HYDROCHLORIDE INJECTION</b>			
<b>(WITHOUT EPINEPHRINE)</b>			
<b>PROCEDURE</b>	<b>CONCENTRATION</b>	<b>VOLUME</b>	<b>TOTAL DOSE</b>
	<b>(%)</b>	<b>(mL)</b>	<b>(mg)</b>
<b>INFILTRATION</b>			
PERCUTANEOUS	0.5 or 1	1 to 60	5 to 300
<b>PERIPHERAL NERVE</b>			
<b>BLOCKS, E.G.</b>			
BRACHIAL	1.5	15 to 20	225 to 300
DENTAL	2	1 to 5	20 to 100
INTERCOSTAL	1	3	30
PARAVERTEBRAL	1	3 to 5	30 to 50
PUDENDAL			
(EACH SIDE)	1	10	100
<b>PARACERVICAL</b>			
<b>OBSTETRICAL</b>			
ANALGESIA			
(EACH SIDE)	1	10	100
<b>SYMPATHETIC NERVE</b>			
<b>BLOCKS, E.G.</b>			
<b>CERVICAL</b>			
(STELLATE GANGLION)	1	5	50
LUMBAR	1	5 to 10	50 to 100

1 THE ABOVE SUGGESTED CONCENTRATIONS AND VOLUMES SERVE ONLY AS  
2 A GUIDE. OTHER VOLUMES AND CONCENTRATIONS MAY BE USED  
3 PROVIDED THE TOTAL MAXIMUM RECOMMENDED DOSE IS NOT EXCEEDED.

#### 4 ***Children***

5 It is difficult to recommend a maximum dose of any drug for children, since this  
6 varies as a function of age and weight. For children over three years of age who  
7 have a normal lean body mass and normal body development, the maximum dose  
8 is determined by the child's age and weight. For example, in a child of five years  
9 weighing 50 lbs., the dose of lidocaine hydrochloride should not exceed 75 to 100  
10 mg (1.5 to 2 mg/lb).

11 In order to guard against systemic toxicity, the lowest effective  
12 concentration and lowest effective dose should be used at all times. In some cases  
13 it will be necessary to dilute available concentrations with 0.9% Sodium Chloride  
14 Injection in order to obtain the required final concentration.

#### 15 ***Sterilization, Storage and Technical Procedures***

16 Disinfecting agents containing heavy metals, which cause release of respective ions  
17 (mercury, zinc, copper, etc.) should not be used for skin or mucous membrane  
18 disinfection as they have been related to incidents of swelling and edema. When  
19 chemical disinfection of multi-dose vials is desired, either isopropyl alcohol (91%)  
20 or ethyl alcohol (70%) is recommended. Many commercially available brands of  
21 rubbing alcohol, as well as solutions of ethyl alcohol not of USP grade, contain  
22 denaturants which are injurious to rubber and therefore are not to be used.

1 Parenteral drug products should be visually inspected for particulate matter  
2 and discoloration prior to administration, whenever the solution and container  
3 permit. The injection is not to be used if its color is pinkish or darker than slightly  
4 yellow or if it contains a precipitate.

5 **HOW SUPPLIED:**

6 Lidocaine Hydrochloride Injection is preserved with 0.1% methylparaben and is  
7 available in the following concentrations:

<b>Product No.</b>	<b>NDC No.</b>	<b>%</b>	<b>Lidocaine HCl mg/mL</b>	<b>Volume (mL)</b>
920102*	63323-201-02	1	10	2
