

**Use of Anticholinergic Agent (atropine or glycopyrronium)**

**22 Highlights do not include all the information needed to use NEOSTIGMINE METHYLSULFATE INJECTION 1.5 mg/mL or 3 mg/mL (0.15 mg/mL or 0.3 mg/mL) single-dose prefilled syringe (2).**

**See full prescribing information for NEOSTIGMINE METHYLSULFATE INJECTION.**

**NEOSTIGMINE METHYLSULFATE Injection, for Intravenous Use**

Initial U.S. Approval: 1939

**INDICATIONS AND USAGE**

Neostigmine Methylsulfate, a cholinesterase inhibitor, is indicated for reversal of the effects of nondepolarizing neuromuscular blocking agents (NMBA) after surgery (1).

**DOSE AND ADMINISTRATION**

**Dosing**

- Should be administered by trained healthcare providers (2)
- Recommends use of a peripheral nerve stimulator to determine whether reversal of neostigmine methylsulfate should be administered and to monitor recovery from neuromuscular blockade (2)
- Neostigmine dosage range is 0.03 mg/kg to 0.5 mg/kg for reversing non-depolarizing neuromuscular block when administered as an anticholinergic agent (atropine or glycopyrronium) (2, 2.1, 2.2, 2.3)
- For reversal of NMBA with surface block, when first twitch response is substantially greater than 10% of baseline, or when a second twitch is present: 0.03 mg/kg by intravenous route (2, 2.2)
- For reversal of NMBA with train-of-four (TOF) or first twitch response is close to 10% of baseline: 0.03 mg/kg by intravenous route (2, 2.2)
- Maximum total dosage is 0.7 mg/kg or to a total of 55 mg for patients in level 2 (2)

An anticholinergic agent, e.g., atropine sulfate or glycopyrronium, should be administered prior to or concurrently with neostigmine methylsulfate (2, 6)

**FULL PRESCRIBING INFORMATION**

**1 INDICATIONS AND USAGE**

Neostigmine Methylsulfate Injection, a cholinesterase inhibitor, is indicated for reversal of the effects of nondepolarizing neuromuscular blocking agents (NMBA) after surgery.

**2 DOSE AND ADMINISTRATION**

**Important Dosing and Administration Instructions**

- Neostigmine should be administered by trained healthcare provider familiar with the use, actions, characteristics, and complications of neuromuscular blocking agents (NMBA) and neuromuscular block reversal agents.
- Prior to Neostigmine Methylsulfate Injection administration and up until completion of normal ventilation, the patient should be well ventilated and a patient airway maintained.
- Use a peripheral nerve stimulator capable of delivering a train-of-four (TOF) stimulus to evaluate the extent of reversal of neuromuscular blockade, and to determine the time of the first dose and the need for additional doses of Neostigmine Methylsulfate Injection.

Prior to the administration of Neostigmine Methylsulfate Injection, there must be a twitch response to the first stimulus in the TOF or at least 10% of baseline (w/ or w/o the response prior to NMBA administration).

Dose selection should be based on the extent of spontaneous recovery or the effect of injection, half-life of the neuromuscular blocking agent (NMBA) to be reversed, and need for NMBA reversal.

Patients should continue to be monitored for adequate reversal of the effects of NMBA for a period of time that would ensure sufficient recovery based on the patient's medical condition and the pharmacokinetics of neostigmine and the NMBA used.

Neostigmine Methylsulfate Injection is administered by intravenous bolus injection. Additional, carefully adjusted doses should be administered according to the patient's response.

An anticholinergic agent (e.g., atropine or glycopyrronium) should be administered prior to or concurrently with Neostigmine Methylsulfate Injection (see Dosage and Administration (2.4), Warnings and Precautions (5.5), and TOF monitoring above) should not be relied upon to determine the adequacy of reversal of neuromuscular blockade. Satisfactory recovery should be judged by the patient's ability to maintain a patent airway, adequate ventilation, and detectable muscle tone.

**2.2 Recommended Dose to Adults**

The recommended dose range of Neostigmine Methylsulfate Injection is 0.03 mg/kg to 0.07 mg/kg administered as an intravenous bolus.

- A dose less than 0.04 mg/kg is recommended for reversal of the effects of NMBA with shorter half-lives (e.g., rocuronium), or when the twitch response to the TOF stimulus is substantially greater than 10% of baseline, or when a second twitch is present.
- A dose of 0.07 mg/kg is recommended for the reversal of the effects of NMBA with longer half-lives (e.g., vecuronium or pancuronium), or when first twitch response is not substantially greater than 10% of baseline, or if there is a need for more rapid recovery.

Additional doses may be required. The recommended maximum total dose is 0.7 mg/kg or up to a total of 55 mg, whichever is less.

**2.3 Recommended Dose to Pediatric Patients, Including Neonates**

Adult guidelines should be followed when Neostigmine Methylsulfate Injection is administered to pediatric patients. Pediatric patients require Neostigmine Methylsulfate Injection doses similar to those for adult patients.

**2.4 Concomitant or Pre-Administration of Anticholinergic Agents**

An anticholinergic agent (e.g., atropine sulfate or glycopyrronium) should be administered intravenously several minutes prior to or concurrently with Neostigmine Methylsulfate Injection administration using separate syringes. For bradycardic patients, the anticholinergic agent should be administered prior to Neostigmine Methylsulfate Injection.

**DOSE FORMS AND STRENGTHS**

Injection: 3 mg per mL (0.15 mg per mL solution) in 1 single-dose prefilled syringe (2)

**CONTRAINDICATIONS**

- Hypersensitivity to neostigmine (4)
- Anterior or mechanical obstruction of the urinary or intestinal tract.

**WARNINGS AND PRECAUTIONS**

**5.1 Bradycardia**

Neostigmine or glycopyrronium should be administered prior to administration of neostigmine methylsulfate injection to lessen risk of bradycardia (5.1)

**5.2 Cardiovascular Complications**

Patients with known cardiac disease, cardiac arrhythmia, or recent coronary artery occlusion may be particularly sensitive to the hemodynamic effects of neostigmine; thus blood pressure and electrocardiogram should be continuously monitored with the initiation of neostigmine treatment and for a duration sufficient to assure hemodynamic stability (5.2)

**5.3 Hypersensitivity (Allergy)**

Can cause a large dose of neostigmine treatment and/or a duration sufficient to assure hemodynamic stability (5.3)

**5.4 Neuromuscular Defunction**

Can cause a large dose of neostigmine treatment and/or a duration sufficient to assure hemodynamic stability (5.4)

**ADVERSE REACTIONS**

The most common adverse reactions include bradycardia and nausea and vomiting (1)

For a complete list of **SUSPECTED ADVERSE REACTIONS**, contact Fresenius Kabi USA, LLC at 1-800-551-7176 or FDA at 1-800-FDA-1088 or www.fda.gov/medwatch

**USE IN SPECIFIC POPULATIONS**

Pregnancy: No human data and limited animal exist. Use only if clearly needed (6)

**Revised: 3/2020**

**7 DRUG INTERACTIONS**

13.6 Pediatric Use

13.7 Geriatric Use

13.8 Toxicology

**14 HOW SUPPLIED/STORAGE AND HANDLING**

14.1 Sections or subsections omitted from the full prescribing information are not listed.

**3 DOSAGE FORMS AND STRENGTHS**

Injection: 3 mg per mL (0.15 mg per mL solution) in 1 single-dose prefilled syringe.

**4 CONTRAINDICATIONS**

Neostigmine methylsulfate is contraindicated in patients with:

- known hypersensitivity to neostigmine methylsulfate, bromine hypersensitivity reactions have included urticaria, angioedema, epiglottitis, generalized rash, facial swelling, peripheral edema, syncope, flushing, hypotension, bronchospasm, bradycardia and anaphylaxis,
- peritonitis or mechanical obstruction of the urinary or intestinal tract.

**5 WARNINGS AND PRECAUTIONS**

**5.1 Bradycardia**

Neostigmine has been associated with bradycardia. An anticholinergic agent (e.g., atropine sulfate or glycopyrronium) should be administered prior to Neostigmine Methylsulfate Injection administration to lessen the risk of bradycardia (see Dosage and Administration (2.4)).

**5.2 Cardiovascular Complications**

Cardiac, arrhythmic, neurogenic, electrocardiogram changes, cardiac arrest, syncope and heart rate complications may be increased with neostigmine methylsulfate. In patients with certain cardiovascular conditions such as coronary artery disease, cardiac arrhythmia or recent acute coronary syndrome, the risk of blood pressure and heart rate complications may be increased. Use of these compounds may also be increased in patients with significant cardiac disease. Standard antagonism with anticholinergic (e.g., atropine) is generally sufficient to mitigate the risk of cardiovascular complications.

**5.3 Hypersensitivity (Allergy)**

Hypersensitivity reactions including anaphylaxis have been reported with neostigmine. Events that appropriate medical management, including epinephrine, cardiopulmonary resuscitation, and medications to treat anaphylaxis, are readily available.

**5.4 Neuromuscular Defunction**

Neuromuscular defunction has been associated with administration of large doses of neostigmine when neuromuscular blockade is minimal. To mitigate the risk of neuromuscular defunction, consider reducing the dose of neostigmine if recovery from neuromuscular blockade is not occurring (5.4)

**5.5 Cholinergic Crisis**

Overdose of neostigmine may cause cholinergic inhibition to respiratory or cholinergic crisis which may be difficult to differentiate from myasthenia crisis since both conditions present with similar symptoms. Both conditions result in extreme muscle weakness, but would rarely affect different tissues. Cholinergic crisis requires immediate withdrawal of all anticholinergic medication. Satisfactory recovery should be judged by the patient's ability to maintain a patent airway, adequate ventilation, and detectable muscle tone.

**6 ADVERSE REACTIONS**

**6.1 Clinical Trial Experience**

Because clinical trials are conducted under widely varying conditions, adverse reaction rates observed in the clinical trials of a drug cannot be directly compared to rates in the clinical trials of another drug and may not reflect the rates observed in practice. The following adverse reactions were described below and elsewhere in the labeling:

- Bradycardia (see Warnings and Precautions (5.1))
- Cardiovascular Complications (see Warnings and Precautions (5.2))
- Hypersensitivity (Allergy) (see Warnings and Precautions (5.3))

Adverse reactions to neostigmine methylsulfate may be most often attributable to exaggerated pharmacological effects, in particular, at muscarinic receptor sites. The use of an anticholinergic agent, e.g., atropine sulfate or glycopyrronium, may prevent or mitigate these reactions.

Quantitative adverse event data are available from trials of neostigmine methylsulfate in which 202 adult patients were exposed to the product. Adverse reactions that occurred with an overall frequency of 1% or greater included the following:

**Adverse: Allergic reactions and anaphylaxis.**

Neurological: Dizziness, syncope, weakness, confusion, loss of consciousness, drowsiness, headache, dysarthria, miosis and visual changes.

**Cardiovascular:** Cardiac arrhythmia including bradycardia, tachycardia, arrhythmogenic block and nodal rhythm, etc. as well as cardiac arrest and hypotension.

**Respiratory:** Increased sputum, pharyngeal and bronchospasm, dyspnea, respiratory depression, epinephrine desaturation, respiratory arrest and bronchospasm.

**Dermatologic:** Diaphoresis, flushing, rash, pruritus, and urticaria.

**Neurological:** Dry mouth, nausea, emesis, flatulence and increased peristalsis.

**General: Increased urinary frequency.**

**Neuroendocrine:** Increased urinary frequency.

**Psychiatric:** Insomnia.

**Genital:** Incontinence on completion, pharyngopyralgia pain, prostatic enlargement, prostatic pain.

**6.2 Post-Marketing Experience**

The following adverse reactions have been identified during post-market use of neostigmine methylsulfate. Because these events are reported infrequently from a population of uncertain size, it is not always possible to reliably estimate their frequency or establish a causal relationship to drug exposure.

**Allergic Disorders:** Allergic reactions, including anaphylaxis.

**Nervous System Disorders:** Confusion, drowsiness, dysarthria, fasciculations, loss of consciousness, miosis, visual changes.

**Cardiovascular Disorders:** Cardiac arrest, cardiac arrhythmia (AV block, nodal rhythm), hypotension, myocardial ECG space, syncope.

**Respiratory, Thoracic and Mediastinal Disorders:** Bronchospasm; increased sputum, pharyngeal and bronchospasm.

**Renal and Urinary Disorders:** Urinary frequency.

**Skin and Subcutaneous Tissue Disorders:** Rash; urticaria; diaphoresis; flushing.

**Gastrointestinal Disorders:** Dry mouth; diarrhea, flatulence; increased peristalsis.

**Reproductive and Sexual Health Disorders:** Urinary frequency.

**Musculoskeletal and Connective Tissue Disorders:** Arthralgia; muscle cramps; spasms; weakness.

**7 DRUG INTERACTIONS**

The pharmacokinetic interaction between neostigmine methylsulfate and other drugs has not been studied. Neostigmine methylsulfate is metabolized by muscarinic enzymes in the liver. Clearly multiple therapy for a longer period of time when using neostigmine methylsulfate may increase the risk of adverse effects, including cholinergic crisis or myasthenia.

**7.1 Depolarizing Muscle Relaxants**

Neostigmine is used to reverse the effects of depolarizing muscle relaxants such as succinylcholine (not recommended, because of the profound phase II block).

**7.2 Antibiotics**

Neostigmine, particularly neostigmine methylsulfate and isoxagmim have neuromuscular blocking action, and therefore, neostigmine dose adjustments may be required to reverse neuromuscular block in patients who have been taking these drugs. There is no effect on neostigmine action on rocuronium reversal by rocuronium, vecuronium, cisatracurium or mivacurium.

**8 USE IN SPECIFIC POPULATIONS**

**8.1 Pregnancy**

**Subcategory**

There are no adequate or well-controlled studies of Neostigmine Methylsulfate Injection in pregnant women. It is not known whether Neostigmine Methylsulfate Injection can cause fetal harm when administered to a pregnant woman or can affect reproduction or cause malformations in the fetus. Data from animal reproduction studies are not considered for use in humans are listed. An pregnancy, regardless of drug exposure, have a background risk of 2 to 4% for major birth defects, and 15 to 20% for any progeny.

Use only if the potential benefits to the mother clearly outweigh the risks to the fetus. The estimated human foetal dose up to 1 mg and 13 mg/kg/day, respectively, ranging from organogenesis (0.1 to 0.2)-times the maximum recommended human dose of 5 mg/kg by weight based on body surface area comparison.

**Anticholinergic drugs,** including neostigmine may cause uterine irritability and induce premature labor when administered to pregnant women near term.

Neostigmine Methylsulfate Injection should be used to a pregnant woman only if clearly needed.

**Data**

**Animal Data**

In embryonal development studies, rats and rabbits were administered Neostigmine Methylsulfate Injection at 0.1 mg/kg and 0.2 mg/kg in a study in rats and 0.1 mg/kg and 0.2 mg/kg in a study in rabbits during Days 6 through Day 22 of gestation, with paws and feet examined on Day 21. There were no adverse effects on physical development, behavior, learning ability, or fertility in the offspring occurred at 0.1 mg/kg which is 0.007 times the MIBD of 1 mg/kg by weight in a rat or a rabbit, respectively, based on maternal body weight (human, rat, rabbit, and primate). The studies resulted in exposure in the animals well below predicted exposures in humans.

In a pre- and post-natal development study in rats, neostigmine methylsulfate was administered to pregnant female rats (Sprague-Dawley) during Days 6 through 22 of gestation at 0.1 mg/kg and 0.2 mg/kg during Days 6 of gestation, with paws and feet examined on Day 21. There were no adverse effects on physical development, behavior, learning ability, or fertility in the offspring occurred at 0.1 mg/kg which is 0.007 times the MIBD of 1 mg/kg by weight in a rat or a rabbit, respectively, based on maternal body weight (human, rat, rabbit, and primate). The studies resulted in exposure in the animals well below predicted exposures in humans.

**8.2 Lactation**

It is not known whether Neostigmine Methylsulfate Injection is excreted in human milk. Because many drugs are excreted in human milk and because of the potential for serious adverse reactions from Neostigmine Methylsulfate Injection in nursing infants, a decision should be made whether to discontinue nursing or to discontinue the drug, taking into account the importance of the drug to the mother.

**8.3 Pediatric Use**

There are no published literature supporting the intravenous use of reversal of nondepolarizing neuromuscular blocking agents in pediatric age groups.

Reversal of neuromuscular blockade with smaller doses of cholinesterase inhibitors in infants and children has been observed. However, infants and small children may be at greater risk of complications from incomplete reversal of neuromuscular blockade and/or from the increased respiratory requirements. The risks associated with incomplete reversal of neuromuscular blockade are increased in children with respiratory muscle weakness. The maximum recommended human dose of 5 mg/kg may be used in children with respiratory muscle weakness. The maximum recommended human dose of 0.07 mg/kg, the usual dose range above, is to be effective in adults, and should be selected using the same criteria as used for adult patients.

Since the blood pressure in pediatric patients, particularly infants and neonates is sensitive to changes in heart rate, the effects of Neostigmine Methylsulfate Injection should be observed prior to administration of neostigmine to lessen the probability of bradycardia and hypotension.

**8.4 Geriatric Use**

There are no studies that have been conducted to determine whether function, which may prolong the duration of action of neostigmine methylsulfate, is different in geriatric patients. However, elderly patients also experience slower spontaneous recovery from neuromuscular blocking action. Therefore, dosage adjustments are generally not needed in geriatric patients. However, they should be monitored for longer periods than younger adults to assure additional doses of Neostigmine Methylsulfate Injection are not required. The duration of monitoring should be prolonged on the basis of duration of action of the neuromuscular blocking agent used on the patient.

**8.5 Renal Impairment**

Elimination half-life of neostigmine was prolonged in anephric patients compared to normal subjects, so neostigmine concentrations may increase in patients with impaired renal function. Although neostigmine methylsulfate is metabolized by injection during a rapid to be warranted in patients with impaired renal function, they should be closely monitored for a longer period of time.

**8.6 Hepatic Impairment**

Because clinical trials are conducted under widely varying conditions, adverse reaction rates observed in the clinical trials of a drug cannot be directly compared to rates in the clinical trials of another drug and may not reflect the rates observed in practice. The following adverse reactions were described below and elsewhere in the labeling:

- Bradycardia (see Warnings and Precautions (5.1))
- Cardiovascular Complications (see Warnings and Precautions (5.2))
- Hypersensitivity (Allergy) (see Warnings and Precautions (5.3))

Adverse reactions to neostigmine methylsulfate may be most often attributable to exaggerated pharmacological effects, in particular, at muscarinic receptor sites. The use of an anticholinergic agent, e.g., atropine sulfate or glycopyrronium, may prevent or mitigate these reactions.

Quantitative adverse event data are available from trials of neostigmine methylsulfate in which 202 adult patients were exposed to the product. Adverse reactions that occurred with an overall frequency of 1% or greater included the following:

**Adverse: Allergic reactions and anaphylaxis.**

Neurological: Dizziness, syncope, weakness, confusion, loss of consciousness, drowsiness, headache, dysarthria, miosis and visual changes.

**Cardiovascular:** Cardiac arrhythmia including bradycardia, tachycardia, arrhythmogenic block and nodal rhythm, etc. as well as cardiac arrest and hypotension.

**Respiratory:** Increased sputum, pharyngeal and bronchospasm, dyspnea, respiratory depression, epinephrine desaturation, respiratory arrest and bronchospasm.

**Dermatologic:** Diaphoresis, flushing, rash, pruritus, and urticaria.

**Neurological:** Dry mouth, nausea, emesis, flatulence and increased peristalsis.

**12 CLINICAL PHARMACOLOGY**

**12.1 Mechanism of Action**

Neostigmine Methylsulfate Injection is a competitive cholinesterase inhibitor. By reducing the breakdown of acetylcholine, neostigmine methylsulfate increases the amount of acetylcholine at the synaptic cleft. This increases the duration of action of nondepolarizing neuromuscular blocking agents, and reverses the neuromuscular blockade.

**12.2 Pharmacokinetics**

Neostigmine is an anticholinesterase agent and inhibits the hydrolysis of acetylcholine by competing with acetylthiocholine for the anionic site of cholinesterase. The inhibition of the breakdown of acetylcholine by neostigmine methylsulfate is reversible. Neostigmine also has direct postsynaptic cholinergic effects which can be managed clinically by the administration of atropine or glycopyrronium.

**12.3 Pharmacokinetics**

**Distribution:**

Protein-binding of neostigmine to human serum albumin ranges from 15 to 25%. The observed volume of distribution is between 0.12 and 0.4 L/kg following intravenous injection.

**Elimination:**

Neostigmine is metabolized in humans in the liver and the observed elimination half-life reported is between 10 and 113 minutes.

**Excretion:**

Neostigmine is metabolized by microsomal enzymes in the liver.

**Specific Populations**

**Geriatric Patients:**

Elimination half-life was prolonged in anephric patients compared to normal subjects, so neostigmine concentrations may increase in patients with impaired renal function. Although neostigmine methylsulfate is metabolized by injection during a rapid to be warranted in patients with impaired renal function, they should be closely monitored for a longer period of time.

**8.5 Renal Impairment**

Elimination half-life of neostigmine was prolonged in anephric patients compared to normal subjects, so neostigmine concentrations may increase in patients with impaired renal function. Although neostigmine methylsulfate is metabolized by injection during a rapid to be warranted in patients with impaired renal function, they should be closely monitored for a longer period of time.

**8.6 Hepatic Impairment**

Because clinical trials are conducted under widely varying conditions, adverse reaction rates observed in the clinical trials of a drug cannot be directly compared to rates in the clinical trials of another drug and may not reflect the rates observed in practice. The following adverse reactions were described below and elsewhere in the labeling:

- Bradycardia (see Warnings and Precautions (5.1))
- Cardiovascular Complications (see Warnings and Precautions (5.2))
- Hypersensitivity (Allergy) (see Warnings and Precautions (5.3))

Adverse reactions to neostigmine methylsulfate may be most often attributable to exaggerated pharmacological effects, in particular, at muscarinic receptor sites. The use of an anticholinergic agent, e.g., atropine sulfate or glycopyrronium, may prevent or mitigate these reactions.

Quantitative adverse event data are available from trials of neostigmine methylsulfate in which 202 adult patients were exposed to the product. Adverse reactions that occurred with an overall frequency of 1% or greater included the following:

**Adverse: Allergic reactions and anaphylaxis.**

Neurological: Dizziness, syncope, weakness, confusion, loss of consciousness, drowsiness, headache, dysarthria, miosis and visual changes.

**Cardiovascular:** Cardiac arrhythmia including bradycardia, tachycardia, arrhythmogenic block and nodal rhythm, etc. as well as cardiac arrest and hypotension.

**Respiratory:** Increased sputum, pharyngeal and bronchospasm, dyspnea, respiratory depression, epinephrine desaturation, respiratory arrest and bronchospasm.

**Dermatologic:** Diaphoresis, flushing, rash, pruritus, and urticaria.

**Neurological:** Dry mouth, nausea, emesis, flatulence and increased peristalsis.

**12.4 Pharmacodynamics**

Neostigmine is metabolized by muscarinic enzymes in the liver. Clearly multiple therapy for a longer period of time when using neostigmine methylsulfate may increase the risk of adverse effects, including cholinergic crisis or myasthenia.

**7.1 Depolarizing Muscle Relaxants**

Neostigmine is used to reverse the effects of depolarizing muscle relaxants such as succinylcholine (not recommended, because of the profound phase II block).

**7.2 Antibiotics**

Neostigmine, particularly neostigmine methylsulfate and isoxagmim have neuromuscular blocking action, and therefore, neostigmine dose adjustments may be required to reverse neuromuscular block in patients who have been taking these drugs. There is no effect on neostigmine action on rocuronium reversal by rocuronium, vecuronium, cisatracurium or mivacurium.

**8 USE IN SPECIFIC POPULATIONS**

**8.1 Pregnancy**

**Subcategory**

There are no adequate or well-controlled studies of Neostigmine Methylsulfate Injection in pregnant women. It is not known whether Neostigmine Methylsulfate Injection can cause fetal harm when administered to a pregnant woman or can affect reproduction or cause malformations in the fetus. Data from animal reproduction studies are not considered for use in humans are listed. An pregnancy, regardless of drug exposure, have a background risk of 2 to 4% for major birth defects, and 15 to 20% for any progeny.

Use only if the potential benefits to the mother clearly outweigh the risks to the fetus. The estimated human foetal dose up to 1 mg and 13 mg/kg/day, respectively, ranging from organogenesis (0.1 to 0.2)-times the maximum recommended human dose of 5 mg/kg by weight based on body surface area comparison.

**Anticholinergic drugs,** including neostigmine may cause uterine irritability and induce premature labor when administered to pregnant women near term.

Neostigmine Methylsulfate Injection should be used to a pregnant woman only if clearly needed.

**Data**

**Animal Data**

In embryonal development studies, rats and rabbits were administered Neostigmine Methylsulfate Injection at 0.1 mg/kg and 0.2 mg/kg in a study in rats and 0.1 mg/kg and 0.2 mg/kg in a study in rabbits during Days 6 through Day 22 of gestation, with paws and feet examined on Day 21. Neostigmine is metabolized by muscarinic enzymes in the liver. Clearly multiple therapy for a longer period of time when using neostigmine methylsulfate may increase the risk of adverse effects, including cholinergic crisis or myasthenia.

**7.1 Depolarizing Muscle Relaxants**

Neostigmine is used to reverse the effects of depolarizing muscle relaxants such as succinylcholine (not recommended, because of the profound phase II block).

**7.2 Antibiotics**

Neostigmine, particularly neostigmine methylsulfate and isoxagmim have neuromuscular blocking action, and therefore, neostigmine dose adjustments may be required to reverse neuromuscular block in patients who have been taking these drugs. There is no effect on neostigmine action on rocuronium reversal by rocuronium, vecuronium, cisatracurium or mivacurium.

**8 USE IN SPECIFIC POPULATIONS**

**8.1 Pregnancy**

**Subcategory**

There are no adequate or well-controlled studies of Neostigmine Methylsulfate Injection in pregnant women. It is not known whether Neostigmine Methylsulfate Injection can cause fetal harm when administered to a pregnant woman or can affect reproduction or cause malformations in the fetus. Data from animal reproduction studies are not considered for use in humans are listed. An pregnancy, regardless of drug exposure, have a background risk of 2 to 4% for major birth defects, and 15 to 20% for any progeny.

Use only if the potential benefits to the mother clearly outweigh the risks to the fetus. The estimated human foetal dose up to 1 mg and 13 mg/kg/day, respectively, ranging from organogenesis (0.1 to 0.2)-times the maximum recommended human dose of 5 mg/kg by weight based on body surface area comparison.

**Anticholinergic drugs,** including neostigmine may cause uterine irritability and induce premature labor when administered to pregnant women near term.

Neostigmine Methylsulfate Injection should be used to a pregnant woman only if clearly needed.

**Data**

**Animal Data**

In embryonal development studies, rats and rabbits were administered Neostigmine Methylsulfate Injection at 0.1 mg/kg and 0.2 mg/kg in a study in rats and 0.1 mg/kg and 0.2 mg/kg in a study in rabbits during Days 6 through Day 22 of gestation, with paws and feet examined on Day 21. There were no adverse effects on physical development, behavior, learning ability, or fertility in the offspring occurred at 0.1 mg/kg which is 0.007 times the MIBD of 1 mg/kg by weight in a rat or a rabbit, respectively, based on maternal body weight (human, rat, rabbit, and primate). The studies resulted in exposure in the animals well below predicted exposures in humans.

In a pre- and post-natal development study in rats, neostigmine methylsulfate was administered to pregnant female rats (Sprague-Dawley) during Days 6 through 22 of gestation at 0.1 mg/kg and 0.2 mg/kg during Days 6 of gestation, with paws and feet examined on Day 21. There were no adverse effects on physical development, behavior, learning ability, or fertility in the offspring occurred at 0.1 mg/kg which is 0.007 times the MIBD of 1 mg/kg by weight in a rat or a rabbit, respectively, based on maternal body weight (human, rat, rabbit, and primate). The studies resulted in exposure in the animals well below predicted exposures in humans.

**8.2 Lactation**

It is not known whether Neostigmine Methylsulfate Injection is excreted in human milk. Because many drugs are excreted in human milk and because of the potential for serious adverse reactions from Neostigmine Methylsulfate Injection in nursing infants, a decision should be made whether to discontinue nursing or to discontinue the drug, taking into account the importance of the drug to the mother.

**8.3 Pediatric Use**

There are no published literature supporting the intravenous use of reversal of nondepolarizing neuromuscular blocking agents in pediatric age groups.

Reversal of neuromuscular blockade with smaller doses of cholinesterase inhibitors in infants and children has been observed. However, infants and small children may be at greater risk of complications from incomplete reversal of neuromuscular blockade and/or from the increased respiratory requirements. The risks associated with incomplete reversal of neuromuscular blockade are increased in children with respiratory muscle weakness. The maximum recommended human dose of 5 mg/kg may be used in children with respiratory muscle weakness. The maximum recommended human dose of 0.07 mg/kg, the usual dose range above, is to be effective in adults, and should be selected using the same criteria as used for adult patients.

Since the blood pressure in pediatric patients, particularly infants and neonates is sensitive to changes in heart rate, the effects of Neostigmine Methylsulfate Injection should be observed prior to administration of neostigmine to lessen the probability of bradycardia and hypotension.

**8.4 Geriatric Use**

There are no studies that have been conducted to determine whether function, which may prolong the duration of action of neostigmine methylsulfate, is different in geriatric patients. However, elderly patients also experience slower spontaneous recovery from neuromuscular blocking action. Therefore, dosage adjustments are generally not needed in geriatric patients. However, they should be monitored for longer periods than younger adults to assure additional doses of Neostigmine Methylsulfate Injection are not required. The duration of monitoring should be prolonged on the basis of duration of action of the neuromuscular blocking agent used on the patient.

**8.5 Renal Impairment**

Elimination half-life of neostigmine was prolonged in anephric patients compared to normal subjects, so neostigmine concentrations may increase in patients with impaired renal function. Although neostigmine methylsulfate is metabolized by injection during a rapid to be warranted in patients with impaired renal function, they should be closely monitored for a longer period of time.

**8.6 Hepatic Impairment**

Because clinical trials are conducted under widely varying conditions, adverse reaction rates observed in the clinical trials of a drug cannot be directly compared to rates in the clinical trials of another drug and may not reflect the rates observed in practice. The following adverse reactions were described below and elsewhere in the labeling:

- Bradycardia (see Warnings and Precautions (5.1))
- Cardiovascular Complications (see Warnings and Precautions (5.2))
- Hypersensitivity (Allergy) (see Warnings and Precautions (5.3))

Adverse reactions to neostigmine methylsulfate may be most often attributable to exaggerated pharmacological effects, in particular, at muscarinic receptor sites. The use of an anticholinergic agent, e.g., atropine sulfate or glycopyrronium, may prevent or mitigate these reactions.

Quantitative adverse event data are available from trials of neostigmine methylsulfate in which 202 adult patients were exposed to the product. Adverse reactions that occurred with an overall frequency of 1% or greater included the following:

**Adverse: Allergic reactions and anaphylaxis.**

Neurological: Dizziness, syncope, weakness, confusion, loss of consciousness, drowsiness, headache, dysarthria, miosis and visual changes.

**Cardiovascular:** Cardiac arrhythmia including bradycardia, tachycardia, arrhythmogenic block and nodal rhythm, etc. as well as cardiac arrest and hypotension.

**Respiratory:** Increased sputum, pharyngeal and bronchospasm, dyspnea, respiratory depression, epinephrine desaturation, respiratory arrest and bronchospasm.

**Dermatologic:** Diaphoresis, flushing, rash, pruritus, and urticaria.

**Neurological:** Dry mouth, nausea, emesis, flatulence and increased peristalsis.

**Myasthenic crisis:** Due to an increase in the severity of the disease, it also accompanied by extreme muscle weakness and may be difficult to distinguish from cholinergic crisis or a myasthenic block. However, such differentiation is extremely important because increase in the dose of neostigmine methylsulfate or other drugs in this crisis, in the presence of cholinergic crisis, could have grave consequences. The type of crisis may be differentiated by the use of edrophonium chloride in the dose as clinical judgment. Treatment of the two conditions differs radically. Without the presence of cholinergic crisis, edrophonium chloride therapy may increase cholinergic crisis and/or the group with the use of edrophonium chloride. The irremediability of atropine in cholinergic crisis is also recommended. Atropine may also be used to lessen the potential side effects of other or muscarinic receptors, but such use by blocking any receptors can lead to treatment reduction of cholinergic crisis.
